- History of Pneumonia
- Interstitial Lung Disease
- Lung Cancer
- Lung Nodules
- Lung Transplants
- Occupational Lung Disease
- Pleural Effusions
- Pulmonary Hypertension
- Pulmonary Tuberculosis
- Sarcoidosis of the Lungs

Proudly Offering Endobronchial Ultrasound (EBUS) Procedures

Endobronchial ultrasound (EBUS) is a minimally invasive yet highly efficient procedure employed for diagnosing conditions such as lung cancer, infections, and other disorders that lead to the enlargement of lymph nodes in the chest.

EBUS enables physicians to perform a technique called transbronchial needle aspiration (TBNA) to procure tissue or fluid samples from the lungs and adjacent lymph nodes, all without the need for traditional surgery. This innovative approach also provides real-time imaging of the airways, blood vessels, lungs, and lymph nodes, along with the added benefit of rapid onsite pathologic evaluation. Patients typically undergo EBUS under moderate sedation or general anesthesia, allowing for a swift recovery and often enabling them to return home on the same day.
